Recipe 1: Defining Database Models and Relationships

Now that you've made some progress with your app, it's time to start modeling the relationships in your database the right way. Your application is evolving, and you need to define how data entities interact. For example, you want each user to be able to write multiple posts (a one-to-many relationship) while each post can be associated with several tags, and each tag can belong to multiple posts (a many-to-many relationship). At a meeting we had recently, your team decided that organizing these relationships would make managing data and running queries easier. Now, we will learn how to build Eloquent models that handle both one-to-many and many-to-many relationships. This way, your app can handle data interactions smoothly and efficiently.

Creating Post and Tag Models

To begin with, we first generate the models along with migration files. For this, simply run:

---

php artisan make:model Post -m
