Recipe 3: Data Seeding for Consistent Testing Scenarios

Now somehow, you may come to a realization that having a consistent and realistic dataset is of much help for testing new features and ensuring that your application behaves as expected. So, during a code review session, your team agreed that simulating real-world data would help identify potential issues early in the development cycle. With this in mind, you decided to use Laravel's seeding functionality to populate your database with test data. So, let us now learn to write seed classes, execute them using Artisan commands, and verify that your database is populated with the required sample data, providing a reliable testing environment.

Creating a Seeder Class

Firstr, run the following to create a new seeder for a relevant model, such as posts:

---

php artisan make:seeder PostsTableSeeder
