Overview

We'll cover how to build a solid foundation for data validation and error management in this chapter. We are going to set up a solid server-side validation system that strictly enforces business rules using Laravel's Validator, making sure that every input meets the required standards. We will learn advanced techniques for creating custom validation rules and generating user-friendly error messages that are tailored to your app's specific needs.

In addition, we are going to make handling exceptions easier by setting up the Handler class to catch and log all errors in the same way. This will keep things running smoothly for users, even when problems pop up. We will also integrate a real-time monitoring solution using Laravel Pulse, which will track and display application errors continuously. This all-in-one approach will help your team figure out, fix, and fix any problems quickly, making your app more stable and performing better overall.
