This change ensures that when an API client sends a request (typically expecting a JSON response), the exception is rendered in a consistent format that includes a success flag, an error message, and the exception details. Otherwise, for standard web requests, Laravel's default error page is returned.

Testing Exception Handling

To test these configurations, you can manually throw an exception in one of your controller methods. For example, add the following line temporarily to simulate an error:

```
throw new \Exception('Testing centralized exception handling.');
```

Then, visit the relevant route via your browser or API client. Use Laravel Debugbar to verify that the exception is logged and the response is properly formatted according to your settings in the **render()** method. This setup captures every unexpected error, logs it appropriately, and returns user-friendly responses based on the request type.
