Summary

During this chapter, you made some great advances in how your app handles data integrity and error management. You started by using Laravel's Validator to make sure every request followed the business rules and data formats. You defined specific validation rules for important fields like username, email, and password, which helped keep data consistent and users secure. Then, you used closures to create custom validation logic, which let you enforce specialized constraints and give users customized error messages.

Later, you centralized exception handling by configuring Laravel's Handler class, which let you capture, log, and gracefully render unexpected errors. You also integrated a real-time monitoring solution by setting up Laravel Pulse, creating a dedicated logging channel, and testing the monitoring functionality through simulated errors. Each step in this chapter built on the last one, so the application validated inputs effectively and also had robust error logging and monitoring. These practices made the app more stable and gave your development team clear, actionable feedback to quickly resolve issues.
