Overview

In this chapter, we will learn to improve your app's responsiveness and user engagement by setting up a solid system for alerts, notifications, and performance monitoring. We are going to learn how to set up in-app alerts using Laravel's Notification system so that users get real-time feedback about critical events. We will also learn how to set up notifications for different channels, like email and text, so that your users get the important updates no matter where they are.

Later, we will integrate push notification capabilities using Laravel Broadcasting with Pusher and Laravel Echo, which will enable instant delivery of messages directly to users' browsers. And finally, we will use Laravel Telescope and Debugbar to keep an eye on key metrics like execution times, memory usage, and query efficiency. So, this chapter is all about giving you the know-how to keep your app running like a well-oiled machine and keep users happy by quickly fixing any hiccups.
