```
    // You could also define toMail() if you plan to support email notifications in the future.

}
```

Here, the notification stores an alert message, a type (like 'info', 'warning', or 'error'), and a timestamp. These details will help you categorize and display the alerts in the UI.

Sending In-App Alerts

Now that you have your notification set up, the next step is to send it to users from your application. In one of your controller methods (for example, in a DashboardController), you can trigger an alert when a specific action occurs. For this, simply open the corresponding controller file and modify a method as follows:

```
namespace App\Http\Controllers;

use App\Models\User;
```
