Conclusion

In this chapter, you put together a full system for alerts, notifications, and performance monitoring in "myapp." You set up in-app alerts using Laravel's Notification system with the database channel, making sure that critical events were instantly visible to users. You set up email and text notifications using Laravel's built-in notification features. You also used Nexmo (or Vonage) credentials to send SMS alerts and customized email content using the MailMessage class. You also integrated push notifications using Laravel Broadcasting with Pusher and Laravel Echo, enabling real-time updates to be sent directly to the client's browser.

Then, you used Laravel Telescope and Laravel Debugbar to keep an eye on system performance metrics like request durations, memory usage, and database query loads. This gave you some great insights into how the application and server were performing. During these steps, you used the tools already installed in your environment, managed via PhpStorm in a Linux setup, to streamline your development process and ensure efficient troubleshooting. This all-in-one approach lets your team keep an eye on how well the app is working, fix problems quickly, and make the user experience better by keeping an eye
