This command should display details about PHP 8.0 and confirms the right version installed.

Installing Composer

Now that PHP is installed, it's time to explore what Composer is? It is considered to be the perfect go-to tool for managing PHP dependencies, since it automatically handles the libraries needed for your project, saving you time and reducing manual errors. With Composer, you can effortlessly download and manage updates to Laravel and its required components.

So now, let's get this Composer on our Linux server. To do this, run:

```
curl -sS https://getcomposer.org/installer -o composer-setup.php
```

This will download the Composer's installer script directly to your current directory. Once the download is complete, verify the integrity of the installer by comparing its hash to the one provided on Composer's official website.
