```
cd myapp
```

Now, let's list the contents of the directory:

```
ls -l
```

We will see a well-organized layout with folders such as and We know that each folder plays a key role. For instance, the **storage** directory is where Laravel writes logs, caches, and files, while **bootstrap/cache** holds crucial cache files that improve performance. The recognition of these components is essential since, as your project evolves, these files and directories become critical for both functionality and security.

Checking Default Permissions

The file permissions on your Linux server dictate who can read, write, or execute your project files. To di this, simply run the following to see the permissions in your project:
