```
ls -l
```

The subsequent output will show you details like **drwxr-xr-x** for each directory. In this notation, we will notice the three sets of permissions for the file owner, group, and others. It's important to note that for Laravel, certain directories, such as **storage** and require write permissions for the web server.

Configuring Directory Permissions

Now, let's secure our Laravel project by ensuring that the web server can appropriately write to critical directories while maintaining a secure overall structure. In our Linux environment, the web server commonly runs under a specific user account such as This means that **storage** and **bootstrap/cache** must be owned by or accessible to this user for proper operation.

Changing Ownership

To do this, run the following command to change the owner and group recursively for the **storage** and **bootstrap/cache** directories:
