Recipe 1: Creating Dynamic Routes and Controller Logic

As you work on your Laravel application "myapp," you notice that as the project grows, static routes aren't enough to handle all the different user requests. So now you have decided that dynamic routing is essential. This approach lets your application interpret and process parameters in the URL, directing requests to the right controllers. So here in this recipe, we will learn how to define dynamic routes in your Laravel project, create the controller logic to match, and integrate a Blade view to render the output. It builds on your previous setup to make sure your application responds intelligently to different inputs.

Setting up a Dynamic Route

To begin with, we first navigate to the project directory “myapp”, and then we open the **routes/web.php** file in our code editor. In this, we need. To add a new route that captures a dynamic segment from the URL using the following code:

```
Route::get('/user/{id}', [App\Http\Controllers\UserController::class, 'show'])->name('user.show');
```
