Controllers with Views in Laravel

Controllers in the MVC architecture are simply classes that group the functionality of one or more routes together. Particularly, if your application is organized in a traditionally CRUD-like fashion, controllers prefer to group related routes together.

A good coding and application development practice is to separate the application logic as per the Model-View-Controller (MVC) logic. It may feel easier to have all logic in the controller, but that will drive away from the purpose and the intention of the MVC architecture.

A controller may manage all the actions that can be performed on a specific resource, such as:

CRUD – Create, Read, Update, Delete

Controllers

The **`make:controller`** Artisan command is used to rapidly create a new controller, and the **`app/Http/Controllers`** directory is where the Laravel application's controllers are kept by default.

For example:

```
php artisan make:controller UserController
```
